# Bayes' Theorem

$$p(Y|X) = \frac{p(X|Y)p(Y)}{p(X)}$$

- Comments:

- Bayes' rule tells us how to 'invert' conditional probabilities, i.e. to find  $P(B|A)$  from  $P(A|B)$ .

# Bayes Network

$$P(L, R, W, S) = P(L)P(R)P(W \mid R)P(S$$

$$P(L, R, W) = P(L)P(R)P(W \mid R)$$

# Bayes Network

$$P(L, R, W, S) = P(L)P(R)P(W \mid R)P(S \mid W)$$

$$P(L, R, W) = P(L)P(R)P(W \mid R)$$

# Bayes Network

B	P(B)
+b	0.001
-b	0.999

E	P(E)
+e	0.002
-e	0.998

A	J	P(J A)
+a	+j	0.9
+a	-j	0.1
-a	+j	0.05
-a	-j	0.95

A	M	P(M A)
+a	+m	0.7
+a	-m	0.3
-a	+m	0.01
-a	-m	0.99

B	E	A	P(A B,E)
+b	+e	+a	0.95
+b	+e	-a	0.05
+b	-e	+a	0.94
+b	-e	-a	0.06
-b	+e	+a	0.29
-b	+e	-a	0.71
-b	-e	+a	0.001
-b	-e	-a	0.999

$$P(+b, -e, +a, -j, +m) =$$

$$P(+b)P(-e)P(+a|+b, -e)P(-j|+a)P(+m|+a)$$

# Conditional independencies in BN

# Hybrid Bayesian Network

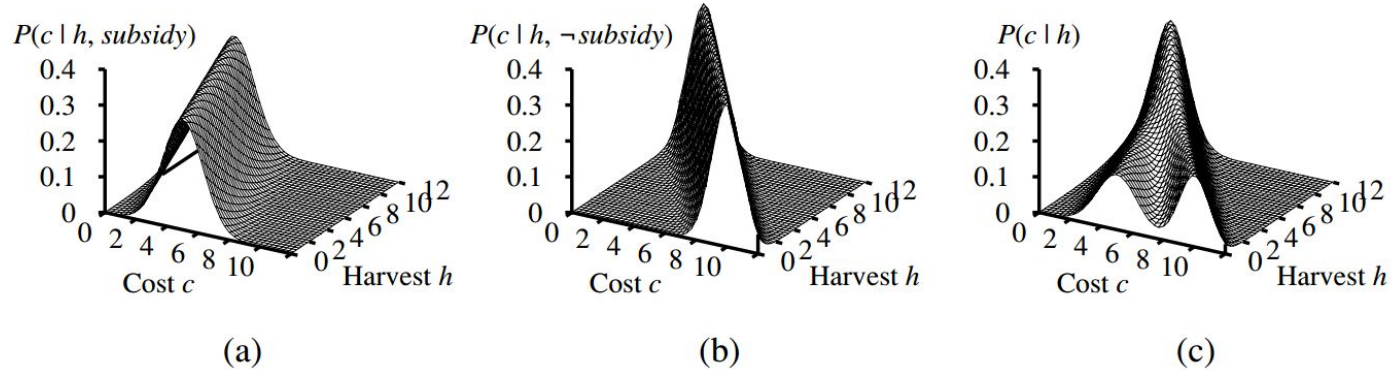

A network with both discrete and continuous variables is called a hybrid Bayesian network. To specify a hybrid network, we have to specify two new kinds of distributions: the conditional distribution for a continuous variable given discrete or continuous parents; and the conditional distribution for a discrete variable given continuous parents.

A simple network with discrete variables(*Subsidy* and *Buys*)and continuous variables (*Harvest* and *Cost*).

# Hybrid Bayesian Network

The graphs in (a) and (b) show the probability distribution over Cost as a function of Harvest size, with Subsidy true and false, respectively. Graph (c) shows the distribution  $P(\text{Cost} \mid \text{Harvest})$ , obtained by summing over the two subsidy cases.

$$P(c \mid h, \text{subsidy}) = N(a_t h + b_t, \sigma_t^2)(c) = \frac{1}{\sigma_t \sqrt{2\pi}} e^{-\frac{1}{2} \left( \frac{c - (a_t h + b_t)}{\sigma_t} \right)^2}$$

$$P(c \mid h, \neg \text{subsidy}) = N(a_f h + b_f, \sigma_f^2)(c) = \frac{1}{\sigma_f \sqrt{2\pi}} e^{-\frac{1}{2} \left( \frac{c - (a_f h + b_f)}{\sigma_f} \right)^2}$$

# Exact Inference in Bayesian Networks

Considering the following equation:

$$\mathbf{P}(X \mid \mathbf{e}) = \alpha \mathbf{P}(X, \mathbf{e}) = \alpha \sum_{\mathbf{y}} \mathbf{P}(X, \mathbf{e}, \mathbf{y})$$

Calculate

$$\mathbf{P}(\textit{Burglary} \mid \textit{JohnCalls} = \textit{true}, \textit{MaryCalls} = \textit{true})$$

$$\mathbf{P}(B \mid j, m) = \alpha \mathbf{P}(B, j, m) = \alpha \sum_e \sum_a \mathbf{P}(B, j, m, e, a, )$$

# Exact Inference in Bayesian Networks

$$P(b \mid j, m) = \alpha \sum_e \sum_a P(b)P(e)P(a \mid b, e)P(j \mid a)P(m \mid a)$$

$$P(b \mid j, m) = \alpha P(b) \sum_e P(e) \sum_a P(a \mid b, e)P(j \mid a)P(m \mid a)$$

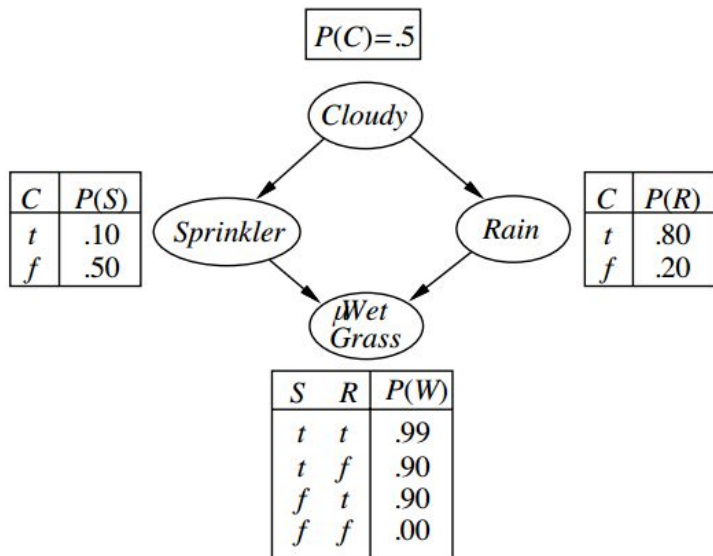

# Exact Inference in Bayesian Networks

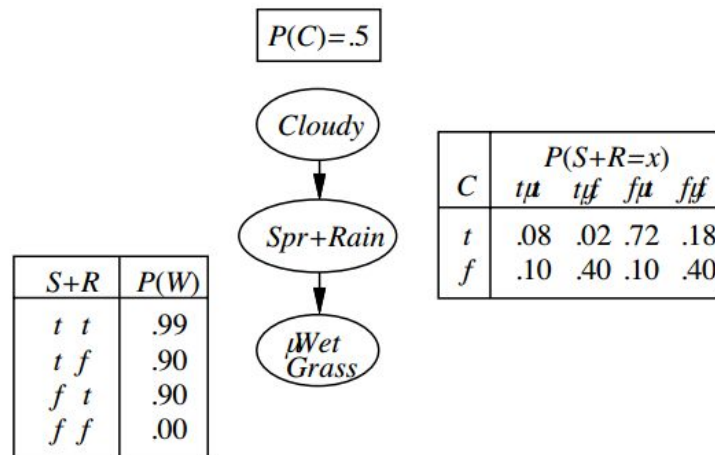

Complexity: NP Hard (generally)

One method: For example, in a polytree network, one would need to issue  $O(n)$  queries CLUSTERING costing  $O(n)$  each, for a total of  $O(n^2)$  time. Using clustering algorithms (also known as JOIN TREE join tree algorithms), the time can be reduced to  $O(n)$ .

## Clustering:

(a)

(b)

# Approximate Inference in Bayesian Networks

## 1. Monte Carlo algorithms.

Markov Chain Monte Carlo

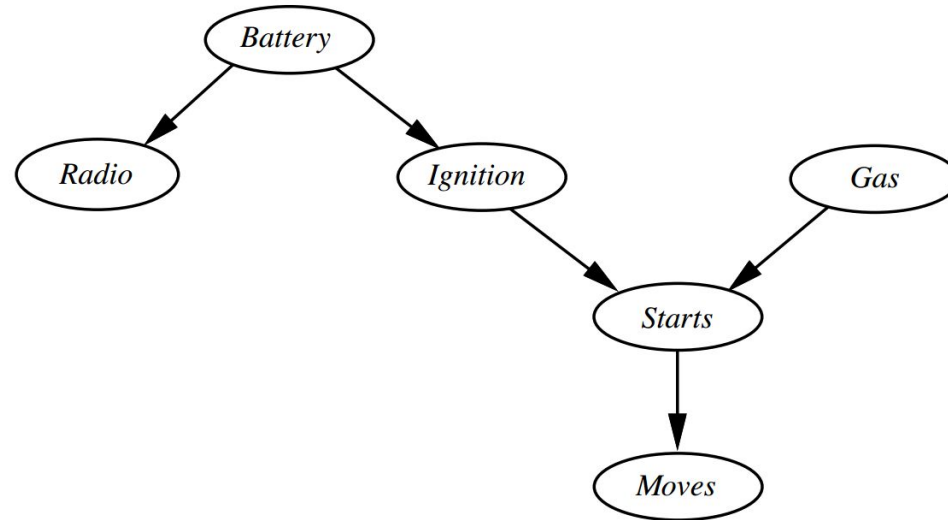

Gibbs Sampler

## 2. Likelihood Weighting

# Exercises

**14.8** Consider the network for car diagnosis shown in Figure 14.21.

- a. Extend the network with the Boolean variables *IcyWeather* and *StarterMotor*.

# Exercises

**14.12** Three soccer teams *A*, *B*, and *C*, play each other once. Each match is between two teams, and can be won, drawn, or lost. Each team has a fixed, unknown degree of quality—an integer ranging from 0 to 3—and the outcome of a match depends probabilistically on the difference in quality between the two teams.

- a. Construct a relational probability model to describe this domain, and suggest numerical values for all the necessary probability distributions.
- b. Construct the equivalent Bayesian network.
- c. Suppose that in the first two matches *A* beats *B* and draws with *C*. Using an exact inference algorithm of your choice, compute the posterior distribution for the outcome of the third match.
- d. Suppose there are  $n$  teams in the league and we have the results for all but the last match. How does the complexity of predicting the last game vary with  $n$ ?

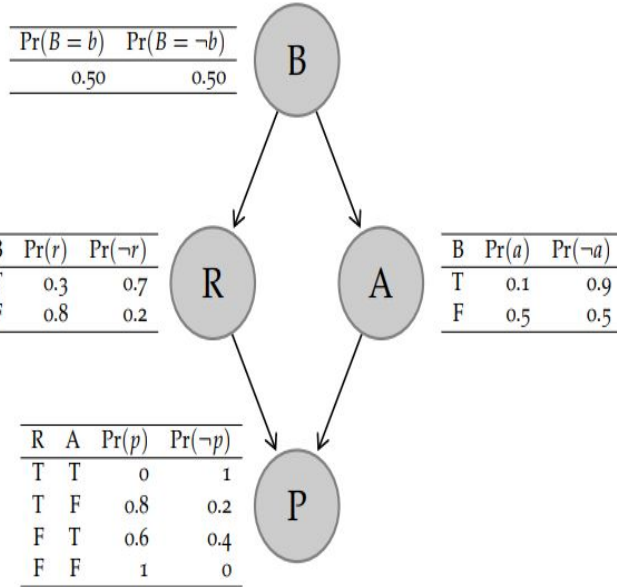

# Exercises

## Exercise 2 – Bayesian Networks – Inference

Figure shows a graphical model with conditional probabilities tables about whether or not you will panic at an exam based on whether or not the course was boring (“B”), which was the key factor you used to decide whether or not to attend lectures (“A”) and revise doing the exercises after each lecture (“R”).

You should use the model to make exact *inference* and answer the following queries:

- what is the probability that you will panic or not before the exam given that you attended the lectures and revised after each lecture?
- what is the probability that you will panic or not before the exam?
- your teacher saw you panicking at the exam and he wants to work out from the model the reason for that. Was it because you did not come to the lecture or because you did not revise?

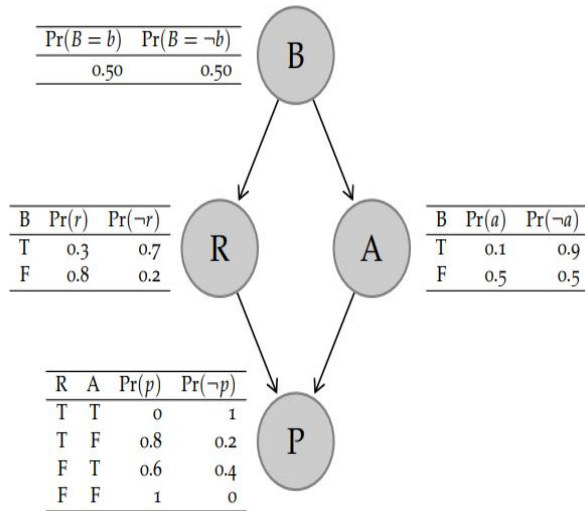

# Exercises

## Solution

what is the probability that you will panic or not before the exam? **Solution**

$$\begin{aligned}
 \Pr(p) &= \sum_{b,r,a} \Pr(b, r, a, p) \\
 &= \sum_{b,r,a} \Pr(b) \Pr(r|b) \Pr(a|b) \Pr(p|r, a) \\
 &= \sum_b \Pr(b) \sum_{r,a} \Pr(r|b) \Pr(a|b) \Pr(p|r, a) \\
 &= 0.5 \cdot (0.3 \cdot 0.1 \cdot 0 + 0.3 \cdot 0.9 \cdot 0.8 + 0.7 \cdot 0.1 \cdot 0.6 + 0.7 \cdot 0.9 \cdot 1) \\
 &\quad + 0.5 \cdot (0.8 \cdot 0.5 \cdot 0 + 0.8 \cdot 0.5 \cdot 0.8 + 0.2 \cdot 0.5 \cdot 0.6 + 0.2 \cdot 0.5 \cdot 1) \\
 &= 0.684
 \end{aligned}$$

# Summary Bayesian Networks

1. A Bayesian network is a directed acyclic graph whose nodes correspond to random variables; each node has a conditional distribution for the node, given its parents.
2. Bayesian networks provide a concise way to represent conditional independence relationships in the domain.
3. A Bayesian network specifies a full joint distribution; each joint entry is defined as the product of the corresponding entries in the local conditional distributions. A Bayesian network is often exponentially smaller than the full joint distribution.
4. Stochastic approximation techniques such as likelihood weighting and Markov chain Monte Carlo can give reasonable estimates of the true posterior probabilities in a network and can cope with much larger networks than can exact algorithms.
